Exterprise website: deployment and maintenance runbook

1. At a glance

What it is	A static website: HTML, CSS and JavaScript files. No server code, database or framework.
Source of truth	GitHub repository **XVOXLABS/Exterprise**, branch `main`
Hosting	**Cloudflare** (Workers static assets, free plan). Deploys automatically on every push to `main`.
Domain and DNS	`exterprise.us`, with DNS on Cloudflare. `www.exterprise.us` is the main address; `exterprise.us` redirects to it.
Build	`tools/build.sh` copies the public files to `dist/` and stamps CSS/JS versions. It runs automatically.
Backup copy	GitHub Pages: https://xvoxlabs.github.io/Exterprise/ (same repository, optional)
Contact forms	The pop-up and the Contact page form send submissions through FormSubmit (formsubmit.co) to contact@exterprise.us (see section 8).
Cost	$0, apart from the domain renewal.

2. Accounts and access (fill this in and keep it current)

Service	Used for	Owner / admins	Notes
GitHub: XVOXLABS org	Code, history, deploy trigger		Turn on 2FA for every member
Cloudflare	Hosting, DNS, SSL, security		Use a company email (not a personal one), 2FA, and at least two admins
Domain registrar (_____)	Owns `exterprise.us`		**Auto-renew ON**, transfer lock ON
Google Search Console	Search indexing and errors		Domain property `exterprise.us`
Bing Webmaster Tools	Bing, ChatGPT search, Copilot		Imported from Search Console

3. What's in the repository

Path	What it is
`*.html`	One file per page (42 pages) plus `404.html`
`style.css` , `site.js`	All styling and behaviour for every page
`assets/`	Images and videos. Keep each file under 25 MB (Cloudflare limit).
`fonts/` , `vendor/`	Web fonts, and the GSAP / ScrollTrigger / Lenis libraries (pinned versions)
`robots.txt` , `sitemap.xml` , `llms.txt` , `llms-full.txt` , `agents.md`	Files for search engines and AI assistants
`_redirects`	Cloudflare permanent redirects (old URLs → new pages)
`_headers`	Cloudflare caching and security headers
`wrangler.jsonc`	Cloudflare hosting configuration
`tools/build.sh`	Deploy build (runs automatically)
`tools/meta.py` , `tools/faq.py` , `tools/seo.py`	Regenerate page titles and descriptions, FAQ sections, SEO tags, the sitemap and the llms files
`tools/stamp-assets.py`	Stamps CSS/JS versions in the repo copy (for the GitHub Pages backup)
`docs/`	This runbook. Not published.

4. One-time setup (about 1 hour, plus up to 24 hours waiting for DNS)

The current website keeps running until step 12, and every step can be undone.

Phase A. Prepare (no change for visitors or email)

1. **Back up the current website** at exterprise.us.
2. **Record the current DNS records** at the domain registrar. A screenshot or export is enough. The critical ones are:
   - **MX** records (email)

- **TXT** records (SPF `v=spf1…`, `_dmarc`, verifications)
- mail **CNAME** records (`autodiscover`, `*._domainkey`, `mail`)

3. **Turn off DNSSEC at the registrar** if it's enabled. You can re-enable it later from Cloudflare.
4. **Create the Cloudflare account** (company email, 2FA on) → **Add a domain** → `exterprise.us` → **Free** plan.
5. **Check the DNS records Cloudflare imported** against step 2, line by line.
   - Add anything missing.
   - Set every mail-related record to **DNS only** (grey cloud).
   - Leave the `@` and `www` records as they are, still pointing at the old site.
6. **Create the hosting.** Go to **Workers & Pages → Create → Import a repository → GitHub**, authorize access to **XVOXLABS/Exterprise**, then set:
   - Production branch: `main`
   - Build command: *(leave empty; it's defined in `wrangler.jsonc`)*
   - Deploy command: `npx wrangler deploy`
   - Root directory: `/`

   Then click **Deploy**. The build log should end with `dist: 247 files …` and a successful deployment.
7. **Turn on preview builds.** In the Worker, go to **Settings → Build** and enable **builds for non-production branches**. Every branch then gets its own preview URL.
8. **Test the `*.workers.dev` URL** Cloudflare shows. Use the checklist in section 6.

Phase B. Move DNS to Cloudflare (no change for visitors)

9. At the registrar, replace the nameservers with the two Cloudflare lists, for example `xxx.ns.cloudflare.com`.
10. Wait for the **"Active"** email from Cloudflare. This usually takes under an hour, at most 24 hours.
11. **Send a test email** to contact@exterprise.us and reply from it.

Phase C. Go live (about 2 minutes; pick a quiet time)

12. In **DNS → Records**, **write down** the existing `www` and `@` records (you need them for a rollback), then delete those two records only.
13. In **Worker → Settings → Domains & Routes → Add → Custom domain**:
    1. Add `www.exterprise.us`.
    2. Add `exterprise.us`.

    Cloudflare creates the DNS records and certificates automatically.

14. Go to **Rules → Redirect Rules → Create rule → template "Redirect from root to WWW"** (301, preserve the path and query).
15. Go to **SSL/TLS → Overview** and set it to **Full (strict)**. Then go to **SSL/TLS → Edge Certificates** and turn on **Always Use HTTPS**.
16. Run the checklist in section 6 against https://www.exterprise.us.

To undo Phase C: remove the two custom domains, then re-create the records from step 12.

Phase D. After go-live

17. **Google Search Console:**
    1. Add a **Domain** property for `exterprise.us` and verify it with the TXT record. Cloudflare can add the record for you automatically.
    2. Submit `https://www.exterprise.us/sitemap.xml`.
18. **Bing Webmaster Tools: Import from Google Search Console**.
19. **Security → Bots:** turn on **Bot Fight Mode**. Do **not** turn on "Block AI Scrapers and Crawlers" unless the business decides to; it stops AI assistants (ChatGPT, Claude, Gemini) reading the site.
20. **Analytics:** go to **Analytics & Logs → Web Analytics** and turn it on (free, no cookie banner needed).
21. Optional: set up a free uptime monitor (for example UptimeRobot) on `https://www.exterprise.us/` with alerts to the team.

---

5. Everyday: deploying a change

1. **Create a branch** and edit the files.
2. **Preview locally** (Node.js 18 or later):

   ```
   npx wrangler dev
   ```

   Then open http://localhost:8787. This runs the real Cloudflare behaviour, including redirects and headers.
3. **If you changed page text, titles, descriptions or FAQs**, regenerate the SEO files:

   ```
   python3 tools/meta.py && python3 tools/faq.py && python3 tools/seo.py && python3 tools/stamp-assets.py
   ```

   - Titles and descriptions live in `tools/meta.py`.
   - FAQ questions and answers live in `tools/faq.py`.
4. **Push the branch and open a pull request.** Cloudflare builds a preview URL for the branch. Review it.
5. **Merge to `main`.** It's live in about a minute. Check **Worker → Deployments** for a green deployment.

Caching (no manual purge needed):

- Pages (`.html`) are never cached, so changes appear immediately.
- `style.css` and `site.js` get a new version stamp on every build automatically.
- Images and videos are cached for up to one week. To replace an image immediately, upload it with a **new file name** and update the reference. Alternatively, go to **Caching → Configuration → Purge Cache → Custom purge** and purge that URL.

Adding a new page:

1. Copy the most similar existing page and change its `<title>` , description, `<h1>` and content.
2. Link to it from the navigation, footer or related pages.
3. Add an entry for it in `tools/meta.py` .
4. Run the commands in step 3 above.

New `.html` files are deployed automatically.

Adding a redirect: add a line to `_redirects` :

```
/old-address /new-page.html 301
```

Adding a new root-level file (for example a verification file): add its name to the `cp` line in `tools/build.sh` , or it won't be deployed. Files inside `assets/` , `fonts/` and `vendor/` are deployed automatically.

---

6. After-deploy checklist (2 minutes)

- ☐ The homepage loads with no errors, on desktop and on a phone.
- ☐ One ServiceNow sub-page, one Smartsourcing sub-page, About and Contact all load.
- ☐ `/contact-us` redirects to `/contact.html` .
- ☐ `/no-such-page` shows the "page not found" page.
- ☐ `/robots.txt` and `/sitemap.xml` load.
- ☐ `exterprise.us` redirects to `https://www.exterprise.us` .
- ☐ Headers are correct:

  ```
  curl -sI https://www.exterprise.us/about.html | grep -i -E "cache-control|strict-transport"
  ```

  This should show `max-age=0, must-revalidate` and `Strict-Transport-Security` .

---

7. Rolling back

1. **Fastest (seconds):** go to **Workers & Pages → exterprise → Deployments**, choose the last good version and **Rollback** / deploy it.
2. **Then fix the code:**

```
git revert <bad-commit-sha>
git push origin main
```

3. **DNS or email problem after a DNS change:** compare **DNS → Records** with the record list from section 4, step 2. Mail records must be **DNS only**.

8. Routine maintenance

When	Task
Every deploy	Section 6 checklist
Monthly	Search Console → **Pages** and **Sitemaps** for errors; Cloudflare build history; uptime alerts
Every January	Update the copyright year in the footer of every page (search for `2021 Exterprise`)
Yearly	Confirm the domain auto-renews and the payment card is valid; review who has access to GitHub and Cloudflare
When needed	Update `vendor/` libraries only deliberately, and test every page afterwards

Contact forms. Both forms (the "Let's Talk" pop-up and the Contact page form) post to FormSubmit (formsubmit.co), which emails every submission to **contact@exterprise.us**. The code is the `v86` block at the top of `site.js` (`window.__xtSend`); the inbox is `window.XT_INBOX`.

- **One-time activation:** the first submission after launch makes FormSubmit send an "Activate form" email to contact@exterprise.us. Click its button once. Until then, submissions are not delivered.
- **Reply:** each email arrives as a table (name, email, company, phone, topics, message, page). Hitting Reply answers the visitor directly.
- **Spam:** a hidden field catches simple bots. If spam grows, add FormSubmit's captcha or move to another service.
- **If sending fails** the visitor sees an error with the email address and keeps what they typed; the form never claims success unless the message was accepted.
- **Switching service** (Formspree, HubSpot, a ServiceNow endpoint): set it on every page before `site.js` loads. The endpoint must accept JSON and answer with a 2×x status:

```
<script>window.XT_FORM_ENDPOINT = "https://…"</script>
```

- **After any change:** submit a test from the live site and confirm the email arrives.

Limits to keep in mind (Cloudflare free plan):

- 25 MB per file; compress videos larger than this before adding them.
- 20,000 files per deployment.
- Static files have unlimited bandwidth.

---

9. Troubleshooting

Symptom	Check
Build failed	Read the build log in Worker → Deployments / Builds. Common causes: a file over 25 MB, or a file in the `cp` list of `tools/build.sh` that was renamed or deleted.
Change not live	Was it merged to `main`? Is the latest deployment green? Do a hard refresh (Ctrl/Cmd + Shift + R).
Old styling after a change	View the page source. The `style.css?v=` value should change after each CSS edit. If it doesn't, check the build log line `style.css?v=…`.
A page returns 404	File names and URLs are case-sensitive. Is the file in the repository root?
`exterprise.us` (without www) doesn't redirect	Rules → Redirect Rules: the "root to WWW" rule must be on, and both custom domains must be attached to the Worker.
Certificate or HTTPS error	SSL/TLS mode must be **Full (strict)**. Custom domains show **Active** in Worker → Domains & Routes.
Email stopped working	DNS → Records: MX and mail TXT/CNAME records exist and are **DNS only**.
Whole site down	Check https://www.cloudflarestatus.com, then roll back (section 7).
